Sir,  
**Response to Ram**

We appreciate the letter from Ram and McDonald (2011) regarding our manuscript.<sup>1</sup>

We understand that this letter questions our statistics. We discussed this issue with our statisticians and would like to argue against the letter.

- (1) A relative risk can be obtained only by cohort study, not by case–control study as performed in our manuscript. Only ‘odds ratio’ can be obtained by case–control study. If Ram does want to work out a relative risk ratio using our data set, probably it will be better to subdivide the group into ‘smokers’ and ‘non-smokers’. Dividing into severe ROP and non-severe ROP groups is not appropriate, as they are just the outcome of the observation. Anyhow, it does not make sense in such a case–control study.
- (2) We would like to explain the meaning of 95% CI. We reported the odds ‘ratio’ for possible risk factors of severe ROP. If the 95% CI of odds ratio includes ‘1’ (not 0) in the interval, it makes the result statistically non-significant. However, the 95% CI for maternal smoking was lower than ‘1’ in our result, which clearly showed statistical significance.

Hence, we would like to say that our statistical analysis was correct. However, we never recommend maternal smoking, owing to a number of smoking-related systemic adverse events in mothers and infants. We reported our results only because they may give insight into some aspects of complicated ROP pathogenesis.

#### Conflict of interest

The authors declare no conflict of interest.

Sir,  
**Serous retinal detachment induced by topical bimatoprost in a patient with Sturge–Weber syndrome**

We report a patient with Sturge–Weber syndrome-associated diffuse choroidal haemangioma who developed serous retinal detachment shortly after starting topical bimatoprost. Cessation of bimatoprost led to complete resolution of the subretinal fluid. This adverse effect of bimatoprost has not been previously reported.

#### Case report

A 16-year-old girl with Sturge–Weber syndrome-associated bilateral diffuse choroidal haemangiomas was referred with a 6-month history of blurred vision in her left eye. She had been treated for ocular hypertension for 11 years and was using timolol/dorzolamide (Cosopt), brimonidine, and bimatoprost for both eyes.

The blurred vision began shortly after switching from latanoprost to bimatoprost in both eyes. Visual acuities were 6/5 in the right and 6/9 in the left eye. Bilateral diffuse choroidal haemangiomas were confirmed on angiography (fluorescein and indocyanine green) and ultrasound. OCT confirmed the presence of significant subretinal fluid inferiorly, which extended to the left fovea, where the changes looked chronic and there was fibrinous deposit (Figures 1a and b).

An adverse effect of bimatoprost was suspected due to its recent introduction and the fact that a similar case related to travoprost had previously been reported.<sup>1</sup> Bimatoprost was therefore stopped and the patient was reviewed 6 weeks later, during which time she noticed subjective visual improvement. Visual acuity had improved to 6/5 in either eye and OCT confirmed complete resolution of the subretinal fluid (Figures 1c and d).

Visual acuity has remained 6/5 in either eye with no subretinal fluid through 1 year of follow-up. Intraocular pressures are controlled on g.Cosopt tds, g.Apraclonidine 0.5% tds, and g.Pilocarpine 2% tds to both eyes.
